

AWS Verified Access (AVA) Tutorial

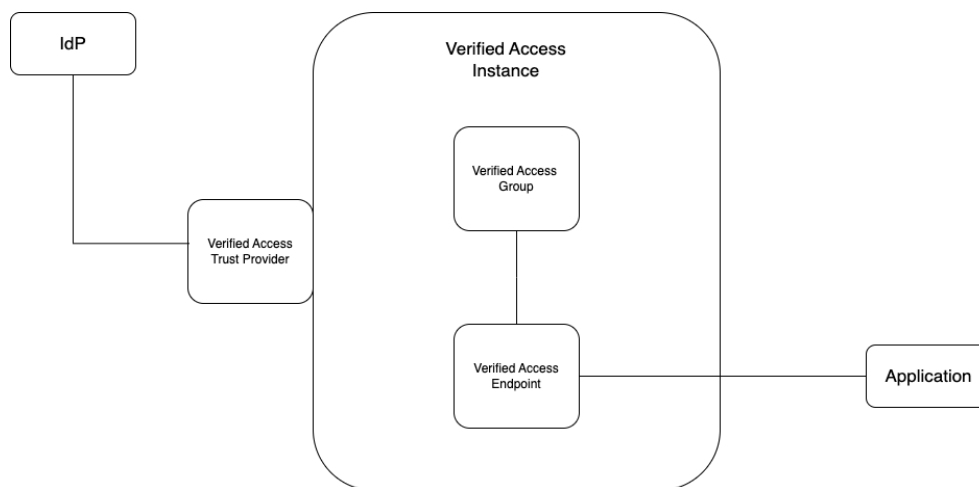

Section 3: Set up your AWS Verified Access Instance

Section Pre-requirements

1. An AWS account
2. AWS cli with permissions to the AWS account
3. An application with a load balancer in front for which to grant verified access (Section 1)
4. An Okta account ready configured with two users and a group (Section 2)

In this next section of the AWS Verified Access (AVA) tutorial, we will use the AWS cli to set up an AWS Verified Access Instance (VAI) that is configured to take trust data—details regarding the security posture of the accessing user—via the Okta account we configured in section 2. We will also set up a group for our endpoint, create that endpoint, and configure it with our application’s domain and load balancer that we created in section 1.

A VAI is the primary AVA object, bringing together **trust data** from trust providers on the one hand, and accessibility to the **application being secured** via AVA endpoint on the other. The group and endpoint policies of the instance arbitrates access, but we won’t address policy until the next section of the tutorial. The purpose of this section of the tutorial is to set up the Verified Access Instance so that it is ready for policy. We do this by configuring the trust provider information with the endpoint information, so that the trust data can be evaluated against the policy we will put in place in the next section.

Step 1: Create a Verified Access Instance

To create a Verified Access Instance (VAI), use the following snippet as a guide:

```
aws ec2 create-verified-access-instance \  
--region us-west-2 \  
--description "test 2022-11-04"
```

For region, add the region in which you want to create the instance. Any string can be used with description.

Upon successfully creating the instance, the description of the instance is returned in the terminal in json:

```
{  
  "VerifiedAccessInstance": {  
    "PrivateAccessInstanceId": "vai-03d91b2d260aa2362",  
    "Description": "test 2022-10-22",  
    "VerifiedAccessTrustProviders": [],  
    "CreationTime": "2022-11-02T16:04:10",  
    "Tags": []  
  }  
}
```

Step 2: Create a Verified Access Trust Provider

The next step is to create a Verified Access trust provider (VATP), so that it can be attached to the VAI we created in Step 1. An account with Okta is required for this step.

First, set the trust-provider-type to user since we are using an IdP like Okta and not an electronic device manager (EDM) for our trust provider. For a policy-reference-name enter anything for the policy reference name. Then enter oidc for user-trust-provider-type. You will need to get the issuer URI for "Issuer=", the AuthorizationEndpoint, TokenEndpoint, UserInfoEndpoint, and both ClientID and ClientSecret from your Okta account (see previous section of this tutorial). The Scope should be set to `openid-profile-email`. Finally set the region to the region you have been using (in this example us-west-2) and add anything that might be helpful in description. Your snippet should resemble the following once filled in with the right information from your own Okta account:

```
aws ec2 create-verified-access-trust-provider \
--trust-provider-type user \
--policy-reference-name mytest \
--user-trust-provider-type oidc \
--oidc-options \
"Issuer=https://dev-64126170-admin.okta.com, \
AuthorizationEndpoint=https://dev-64126170-admin.okta.com/oauth2/v1/authorize
, \
TokenEndpoint=https://dev-64126170-admin.okta.com/oauth2/v1/token, \
UserInfoEndpoint=https://dev-64126170-admin.okta.com/oauth2/v1/userinfo, \
ClientId=0oa5p3ds510m0CHa95d7, \
ClientSecret=SwTIPCPV8b1k_C4nZ4lP8U0IqGb14jQIXPr9ue8v, \
Scope='openid-profile-email'" \
--region us-west-2 \
--description "test 2022-11-17"
```

When successfully created, the following output describing the new trust provider is returned:

```
{
  "VerifiedAccessTrustProvider": {
    "VerifiedAccessTrustProviderId": "patp-0181545674e7fa5e2",
    "Description": "test 2022-10-25",
    "TrustProviderType": "user-identity",
    "UserIdentityType": "oidc",
    "OidcOptions": {
      "Issuer": "https://dev-64126170-admin.okta.com",
      "AuthorizationEndpoint":
"https://dev-64126170-admin.okta.com/oauth2/v1/authorize",
      "TokenEndpoint": "https://dev-64126170-admin.okta.com/oauth2/v1/token",
      "UserInfoEndpoint":
"https://dev-64126170-admin.okta.com/oauth2/v1/userinfo",
      "ClientId": "0oa5p3ds510m0CHa95d7",
      "ClientSecret": "SwTIPCPV8b1k_C4nZ4lP8U0IqGb14jQIXPr9ue8v",
      "Scope": "openid,profile,email"
    },
    "PolicyReferenceName": "my-test",
    "CreationTime": "2022-11-02T16:05:32",
    "Tags": []
  }
}
```

However, although it is created, we still need to attach our VATP to our VAI.

Step 3: Attach the Verified Access Trust Provider to the Verified Access Instance

Next, attach the VATP to the VAI using the VAI id and VATP id:

```
aws ec2 attach-verified-access-trust-provider \  
--verified-access-instance-id vai-095721eb16051df79 \  
--verified-access-trust-provider-id vatp-091f0e4a90c4489aa \  
--region us-west-2
```

We need to attach the VATP we made to the VAI we made so that the VAI knows to receive trust data from this trust provider. It is attachable and detachable in case you want to switch out trust providers for your VAI. You can also attach more than one trust provider for extra security.

A successful attachment should return output similar to the following, showing both the information for the VATP as well as the VAI:

```
{  
  "VerifiedAccessTrustProvider": {  
    "VerifiedAccessTrustProviderId": "vatp-035b00fa6d58ae542",  
    "Description": "test 2022-11-17",  
    "TrustProviderType": "user",  
    "UserTrustProviderType": "oidc",  
    "OidcOptions": {  
      "Issuer": "https://dev-64126170-admin.okta.com",  
      "AuthorizationEndpoint": "https://dev-64126170-admin.okta.com/oauth2/v1/authorize",  
      "TokenEndpoint": "https://dev-64126170-admin.okta.com/oauth2/v1/token",  
      "UserInfoEndpoint":  
        "https://dev-64126170-admin.okta.com/oauth2/v1/userinfo",  
      "ClientId": "00a5p3ds510m0CHa95d7",  
      "ClientSecret": "SwTIPCPV8b1k_C4nZ4lP8U0IqGb14jQIXPr9ue8v",  
      "Scope": "openid-profile-email"  
    },  
    "PolicyReferenceName": "mytest",  
    "CreationTime": "2022-11-18T01:14:18",  
    "LastUpdatedTime": "2022-11-18T01:14:18"  
  },  
  "VerifiedAccessInstance": {  
    "VerifiedAccessInstanceId": "vai-0f23e65bedd60fc55",  
    "Description": "test 2022-11-04",  
  }  
}
```

Step 4: Create an AWS Verified Access Group

Next, we will create an AWS Verified Access *group*, an object by which we can group different resources we want to access using the same security posture. All endpoints (what we will create in the step 5 below) require an AWS Verified Access group (VAG) to create. While you can have finer grained policy at the resource/endpoint level itself, all endpoints must have some group level policy.

To create a VAG, you need only have the VAI id from the instance we created in Step 1. This information should have been outputted by the terminal via the last step where we attached the VATP to the VAI, but you can also retrieve id by running `aws ec2 describe-verified-access-instances` (assuming you have only created the one instance as we have in this tutorial so far).

Once you have the VAI id, add this, a description, and the region you have been using to complete the following command to create the group:

```
aws ec2 create-verified-access-group \
--verified-access-instance-id vai-095721eb16051df79 \
--description "test 2022-11-18" \
--region us-west-2
```

When successful, you will see receive something like the following:

```
{
  "VerifiedAccessGroup": {
    "VerifiedAccessGroupId": "vagr-0edc1d7b577ebe455",
    "VerifiedAccessInstanceId": "vai-095721eb16051df79",
    "Description": "test 2022-11-18",
    "Owner": "780868906563",
    "VerifiedAccessGroupArn":
"arn:aws:ec2:us-west-2:780868906563:verified-access-group/vagr-0edc1d7b577ebe455",
    "CreationTime": "2023-01-09T18:43:48",
    "Tags": []
  }
}
```

Step 5: Create a Verified Access Endpoint

Next we will create an endpoint associated with the group we just made. For this we will need the VAG id from the previous step's output (you can also use `aws ec2 describe-verified-access-groups` to retrieve the ID).

AVA only supports `endpoint-type load-balancer`, so include this in the next line as shown below. The attachment type is `vpc`. You should use the `domain-certificate-arn` you created in Section 1 of this tutorial here. The `application-domain` should be the URI of the application for which you are trying to set up Verified Access (see Section 1 for details) and the `endpoint-domain-prefix` is something you create. Under `load-balancer-options`, you will need the `arn` for the load balancer for your application domain (see Section 1 for details). Finally, you need the `Port` to be 8080, `Protocol=http`, as well as the subnet information for the application domain, which you should have recorded in Section 1 of this tutorial.

```
aws ec2 create-verified-access-endpoint \
--verified-access-group-id vagr-0edc1d7b577ebe455 \
--endpoint-type load-balancer \
--attachment-type vpc \
--domain-certificate-arn
arn:aws:acm:us-east-1:321319525489:certificate/3b128c67-633f-4617-a9ee
-8fc7e5a18047 \
--application-domain earlenba.people.aws.dev \
--endpoint-domain-prefix test-2022-10-14 \
--load-balancer-options \
"LoadBalancerArn=arn:aws:elasticloadbalancing:us-east-1:321319525489:el
oadbalancer/app/test-2022-10-14/2e4e1f9eb5647781, \
Port=8080, \
Protocol=http, \
SubnetIds=subnet-0d6b28e56de414ccc" \
--description "test 2022-10-14" \
--region us-west-2
```

As with the other AVA objects, you will receive output describing the new endpoint upon successful creation.

Summary and Next Section

We have now set up our AVA instance with an AVA group that can be secured for a group of endpoints, an AVA endpoint to be secured on its own, and an AVA trust

provider attached to our instance to provide authorization to those allowed to access the application domain.

Next, in the final section of this tutorial, we will put some policy in effect so that we can access our endpoint. If we do not do this, as it is now all requests will be denied, as the policy engine that AVA relies upon denies access as a default. Once we have this policy in place, we can then test our connection using a user who should have access and one that should not.
